

CS301 Computer Architecture

DR GAYATHRI ANANTHANARAYANAN

gayathri@iitdh.ac.in

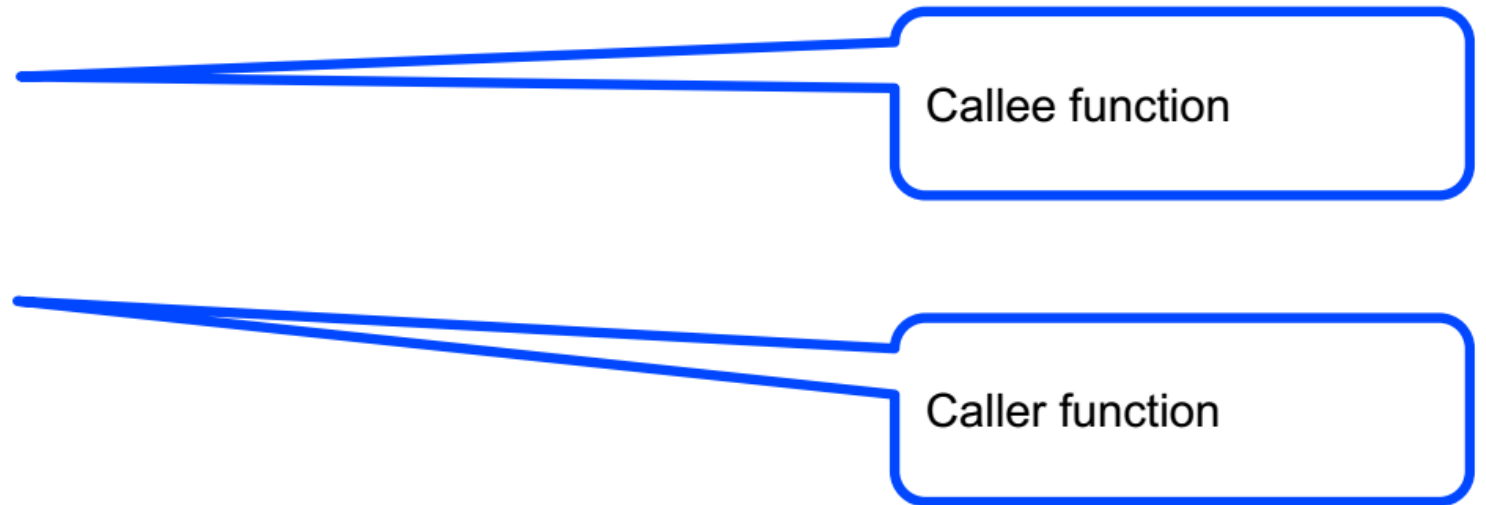

Materials in these slides are borrowed from textbooks and existing Architecture courses

Functions

- Instruction sequence that is used frequently
- Typically invoked in more than one context
 - Can even invoke itself
- Notion of input arguments
- Notion of return values
- Notion of state

Example

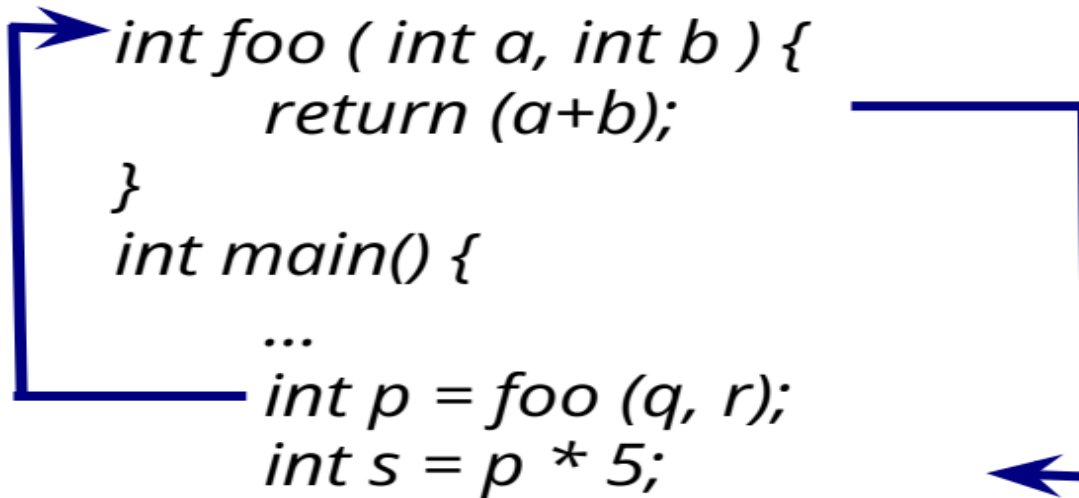

```
int foo ( int a, int b ) {  
    return (a+b);  
}  
int main() {  
    ...  
    int p = foo (q, r);  
    int s = p * 5;  
    ...  
    int w = foo (x, y);  
    int z = w - 3;  
    ...  
}
```

Callee function

Caller function

Example

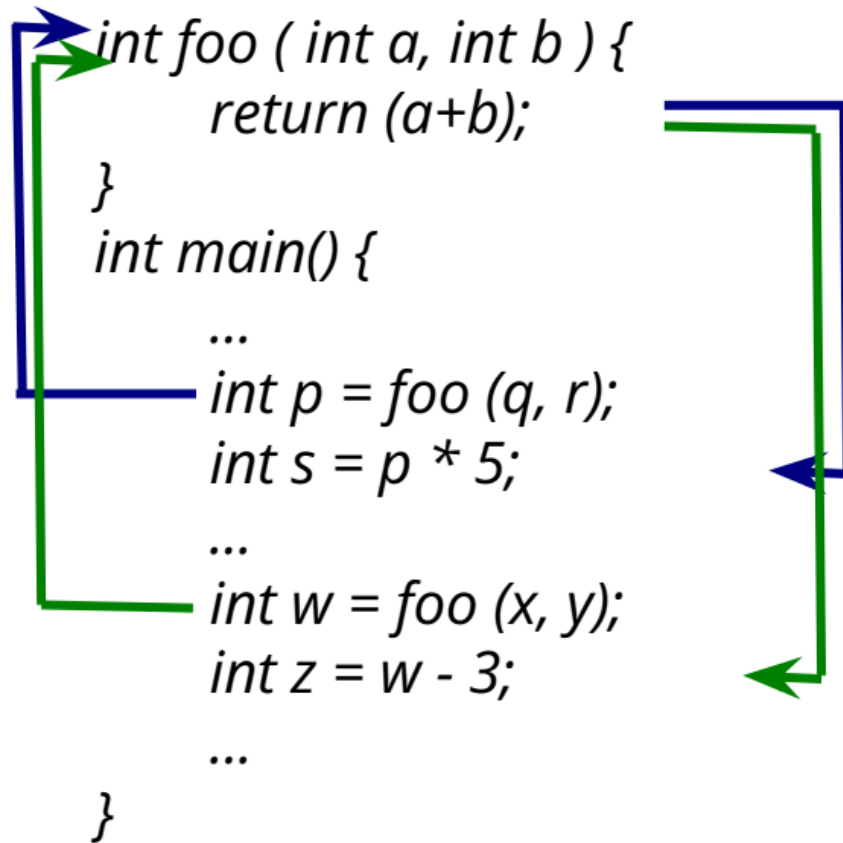

```
int foo ( int a, int b ) {  
    return (a+b);  
}  
int main() {  
    ...  
    int p = foo (q, r);  
    int s = p * 5;  
    ...  
    int w = foo (x, y);  
    int z = w - 3;  
    ...  
}
```

The diagram illustrates the execution flow of the provided C code. A blue arrow originates from the `foo` function definition and points to the first call to `foo` within the `main` function, specifically the line `int p = foo (q, r);`. Another blue arrow originates from the right side of the code block and points to the second call to `foo` within the `main` function, specifically the line `int w = foo (x, y);`. These arrows indicate the sequence of function calls during program execution.

Example

Control Flow

The diagram illustrates control flow between two functions. A blue arrow starts at the `int p = foo(q, r);` line in `main` and points to the start of the `foo` function. A green arrow starts at the `int w = foo(x, y);` line in `main` and also points to the start of the `foo` function. Both arrows return from the `foo` function back to the `main` function, with the blue arrow returning to the line following `int p = foo(q, r);` and the green arrow returning to the line following `int w = foo(x, y);`.

```
int foo ( int a, int b ) {  
    return (a+b);  
}  
  
int main() {  
    ...  
    int p = foo (q, r);  
    int s = p * 5;  
    ...  
    int w = foo (x, y);  
    int z = w - 3;  
    ...  
}
```

```
.foo:  
0x1234 ...  
0x1238 ret  
  
...  
.main:  
0x2000 ...  
...  
0x2040 call .foo  
0x2044 ...  
...  
0x2100 call .foo  
0x2104 ...  
...
```

Implementing Functions

- * Functions are blocks of assembly instructions that can be repeatedly invoked to perform a certain action
- * Every function has a starting address in memory (e.g. foo has a starting address A)

Implementing Functions - II

- * To call a function, we need to set :
 - * $pc \leftarrow A$
- * We also need to store the location of the pc that we need to come to after the function returns
- * This is known as the **return address**
- * We can thus call any function, execute its instructions, and then return to the saved **return address**

Notion of the Return Address

- * PC of the call instruction $\rightarrow p$
- * PC of the return address $\rightarrow p + 4$

because, every instruction takes 4 bytes

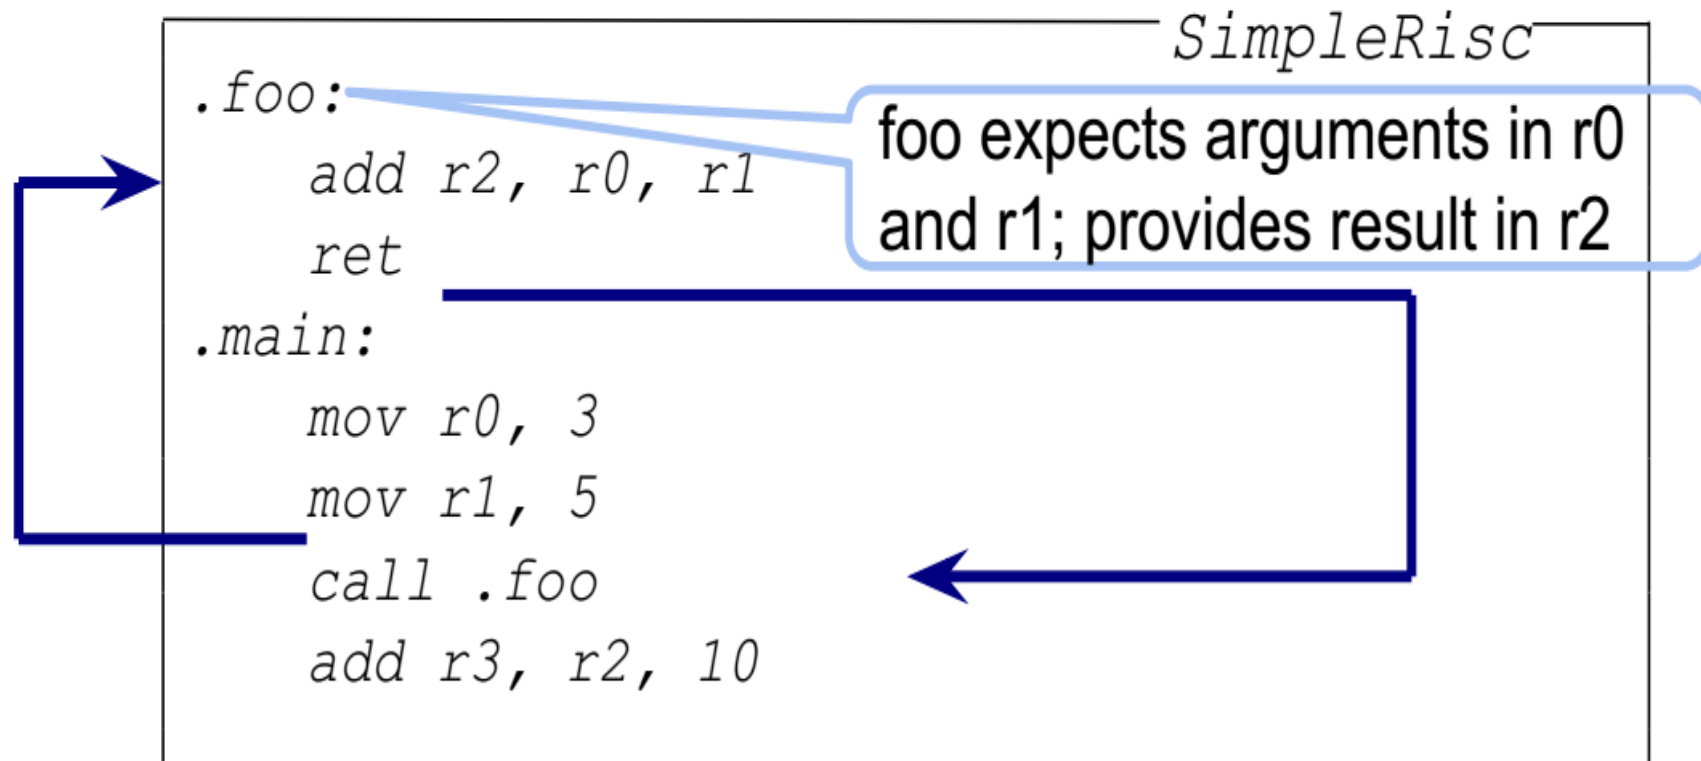

Two New Instructions in the ISA

1. call .foo
 - a. $ra \leftarrow PC + 4$
 - b. $PC \leftarrow \text{address}(.foo)$
2. ret
 - a. $PC \leftarrow ra$

Remember:
“ra” or the Return Address
register is the same as r15

How do we pass arguments/ return values

- * Solution : use registers

Problems with this Mechanism

* Space Problem

- * We have a limited number of registers
- * We cannot pass more than 16 arguments

```

int factorial ( int n ) {
    if ( n == 1 )
        return n;
    else
        return n * factorial ( n - 1 );
}
int main() {
    factorial ( 3 );
}

```

```

.factorial:
0x1000      cmp  r2, 1
0x1004      beq  .done
0x1008      mov  r3, r2
0x100c      sub  r2, r2, 1
0x1010      call .factorial
0x1014      mul  r1, r1, r3
0x1018      ret
.done:
0x101c      mov  r1, 1
0x1020      ret
...
.main:
0x2000      mov  r2, 3
0x2004      call .factorial

```

**factorial
expects
argument in
r2; provides
result in r1**

```

int factorial ( int n ) {
    if ( n == 1 )
        return n;
    else
        return n * factorial ( n - 1 );
}

int main() {
    factorial ( 3 );
}

```

Value of r3, which constituted the “state” of the particular invocation/ call of the function, is getting lost.

```

.factorial:
0x1000    cmp  r2, 1
0x1004    beq  .done
0x1008    mov  r3, r2
0x100c    sub  r2, r2, 1
0x1010    call .factorial
0x1014    mul  r1, r1, r3
0x1018    ret
.done:
0x101c    mov  r1, 1
0x1020    ret
...
.main:
0x2000    mov  r2, 3
0x2004    call .factorial

```

factorial expects argument in r2; provides result in r1

Problems with this Mechanism

* Space Problem

- * We have a limited number of registers
- * We cannot pass more than 16 arguments
- * **Solution** : Use memory also

* Overwrite Problem

- * What if a function calls itself ? (recursive call)
- * The callee can **overwrite** the registers of the caller
- * **Solution** : Spilling

Register Spilling

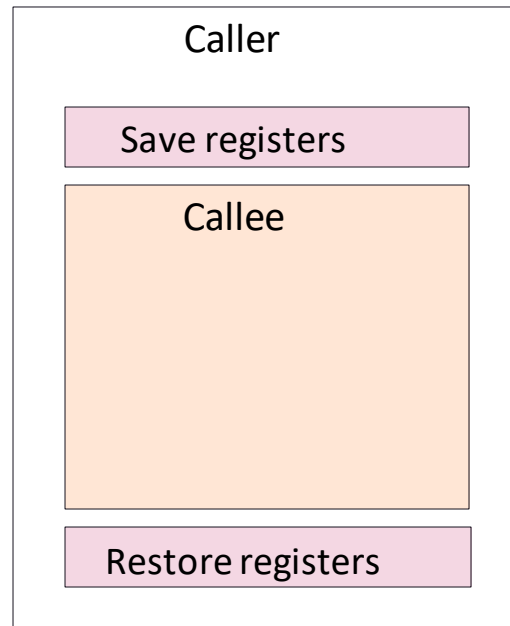

- * The notion of **spilling**

- * The caller can **save** the set of registers its needs
- * **Call** the function
- * And then **restore** the set of registers after the function returns
- * Known as the **caller saved scheme**

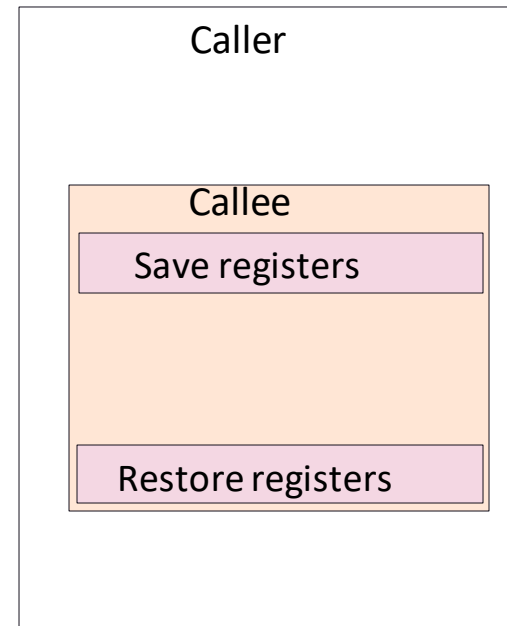

- * **callee saved scheme**

- * The callee **saves**, the registers, and later **restores** them

Spilling

(a) Caller saved

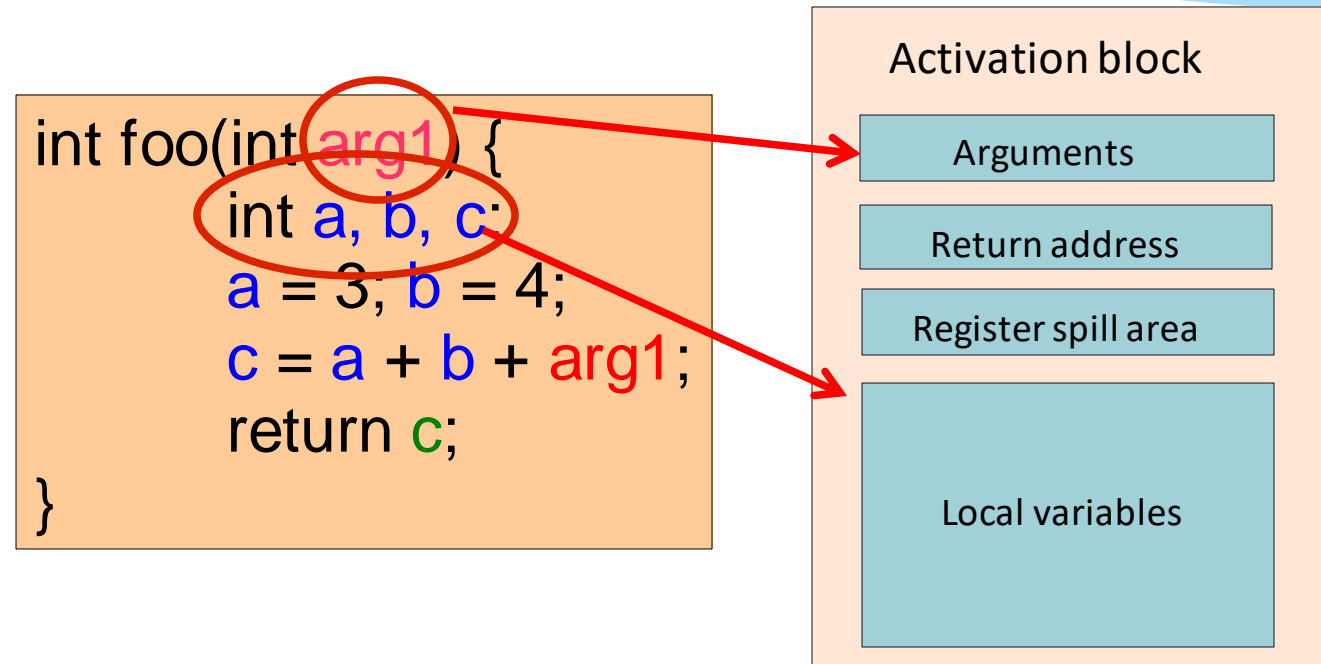

(b) Callee saved

Problems with our Approach

- * Using memory, and spilling solves both the **space problem** and **overwrite problem**
- * However, there needs to be :
 - * a strict agreement between the caller and the callee regarding the set of **memory locations that need to be used**
 - * Secondly, after a function has finished execution, all **the space that it uses needs to be reclaimed**

Activation Block

- * **Activation block** → memory map of a function
arguments, register spill area, local vars

How to use activation blocks ?

- * Assume caller saved spilling
- * Before calling a function : **spill the registers**
- * **Allocate the activation block** of the callee
- * **Write the arguments** to the activation block of the callee, if they do not fit in registers
- * **Call the function**

Using Activation Blocks - II

- * In the called function
 - * Read the arguments and transfer to registers (if required)
 - * Save the return address if the called function can call other functions
 - * Allocate space for local variables
 - * Execute the function
- * Once the function ends
 - * Restore the value of the return address register (if required)
 - * Write the return values to registers, or the activation block of the caller
 - * Destroy the activation block of the callee

Using Activation Blocks - III

- * Once the function ends (contd ...)
 - * Call the **ret** instruction
 - * and return to the caller
- * **The caller :**
 - * **Retrieve the return values** from the registers of from its activation block
 - * **Restore** the spilled registers
 - * **continue ...**
